July 20 - 22, 2020

A system design methodology

# Top-down functional composition

[www.incosymp2020.org](http://www.incosymp2020.org)

Johan Bredin, SAAB Aeronautics  
*johan.bredin@saabgroup.com*

# This presentation includes

- A critical view on the top-down decomposition methodology
- A new top-down composition design methodology, including:
  - Executable design- and integration models
  - Very early and continuous design integration

Very early and continuous verification of

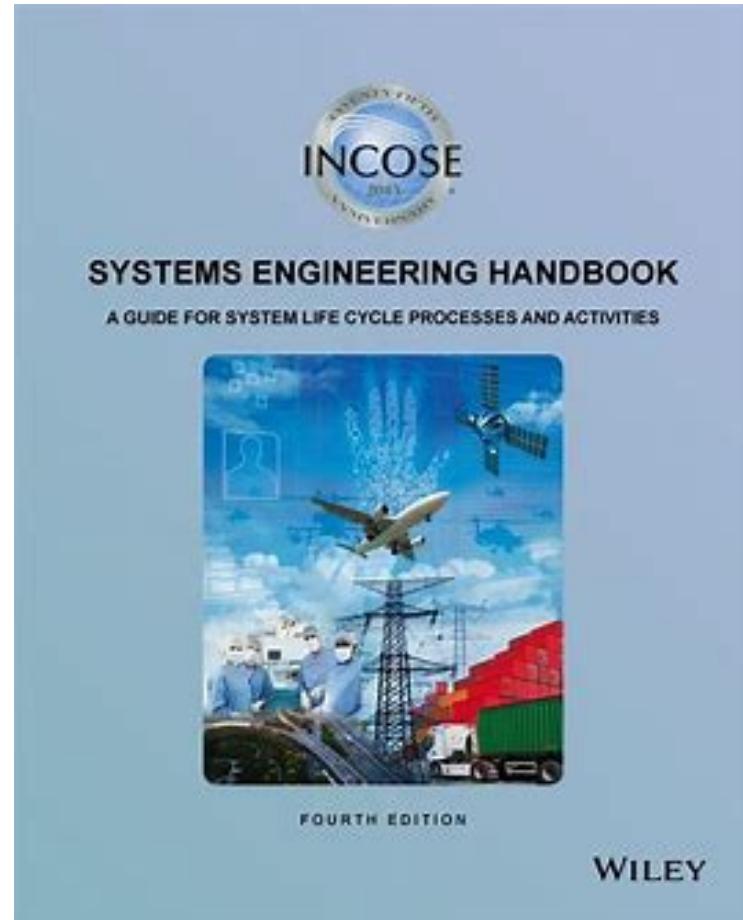

# My background

- 15 years as a software developer
  - Mainly code generation from UML models
  - Manual coding
  - Most of the time: safety critical software for avionics applications
- 6 years as a MBSE methodology developer / support person

# The handbook

Problem understanding the requirements, architecture and design processes

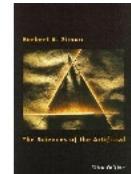

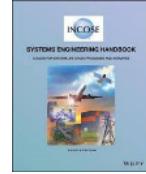

# Part One : Decomposition

- **Where I argue that a system design approach based on functional decomposition can not produce good requirements.**
- This is a problem because requirements is the foundation on which systems are built.
- Warning: this may feel a little bit uncomfortable.

# Legend

- INCOSE SE Handbook, 4th edition
- Engineering Systems (Buede & Miller, 2016)
- The sciences of the artificial (Simon, 1996)
- Yours truly

# Two premises that need to be true

- P1 : *All requirements sets is complete*

- P2 : *All requirements sets is design-agnostic*

- P2 means that one shall not make design choices while writing requirements

# Questioning Premise P1

- P1 : *All requirements sets is complete*

# Recursively applied requirements process

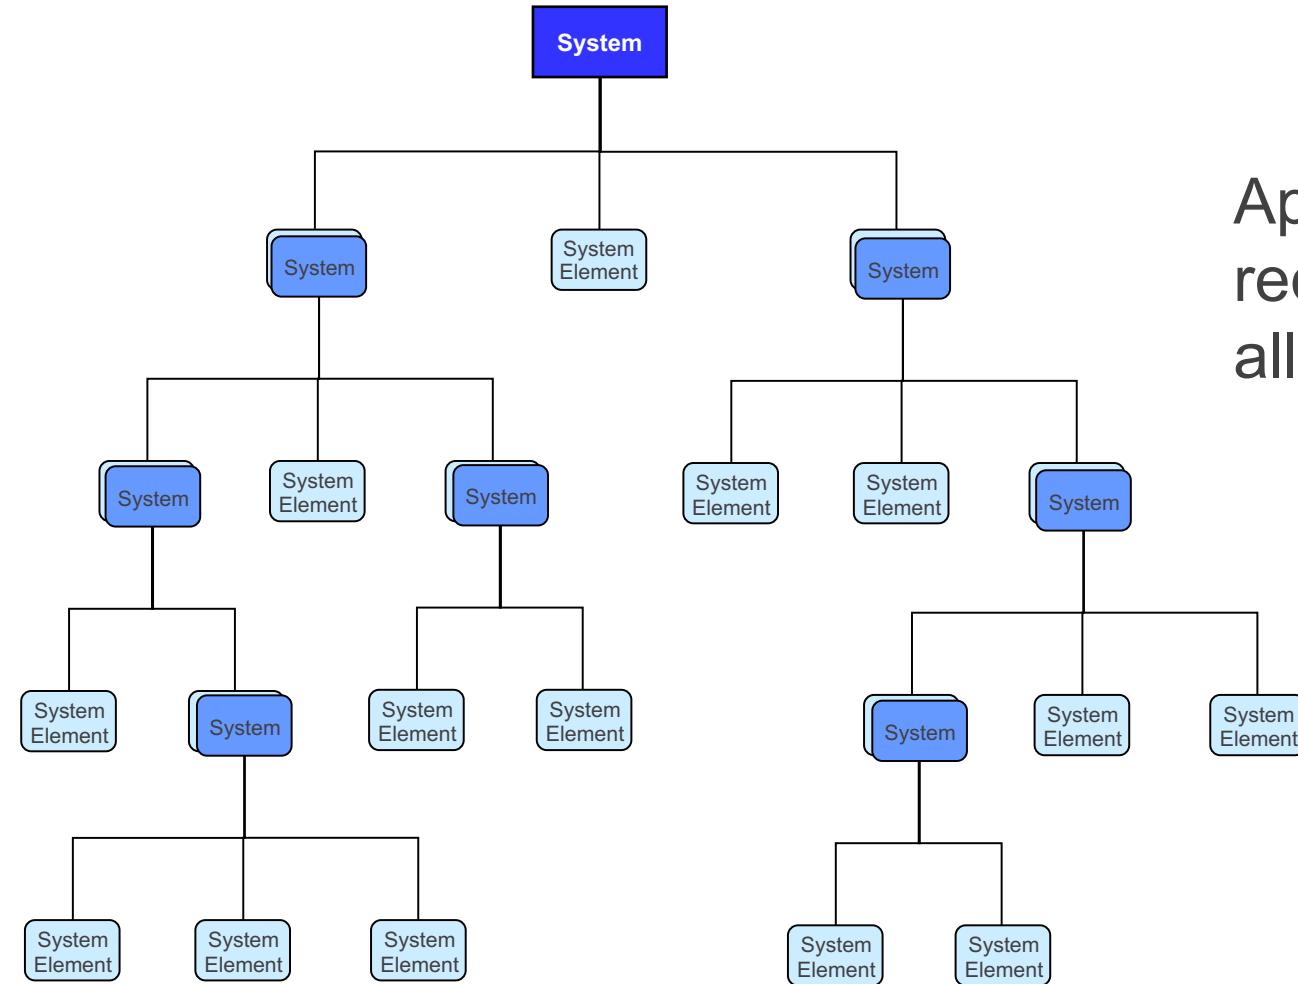

- P3 : Complex/complicated systems require system internal hierarchies
- P4 : System hierarchies require a recursively applied requirements process
- P5 : The system under consideration is complex/complicated

{P3, P4, P5} => C1 :The system requirements process shall be recursively applied.

# System hierarchy

Apply the same system requirements process for all systems / system elements

# Transformation of inputs into outputs

- C1: The system requirements process shall be recursively applied.
- P6 : A system function implies transformation of inputs into outputs

# Functional decomposition

- P8: Inputs and outputs from higher level system nodes must be conserved if the methodology *functional decomposition* is used.

**"This decomposition process must conserve all of the inputs to and all of**

# Back to the future

- P8: Inputs and outputs from higher level system nodes must be conserved if the methodology ***functional decomposition*** is used.
- C2: A system requirements set, on all system levels, includes transformation of inputs into outputs

# Back to the future – failure of P1

- P1 : *All requirements sets is complete*
- C3 : The transformation of the (to be) realized systems inputs to the (to be) realized systems outputs must be specified in the top-level requirements set.

# Questioning Premise P2

- P2 : *All requirements sets is design-agnostic*

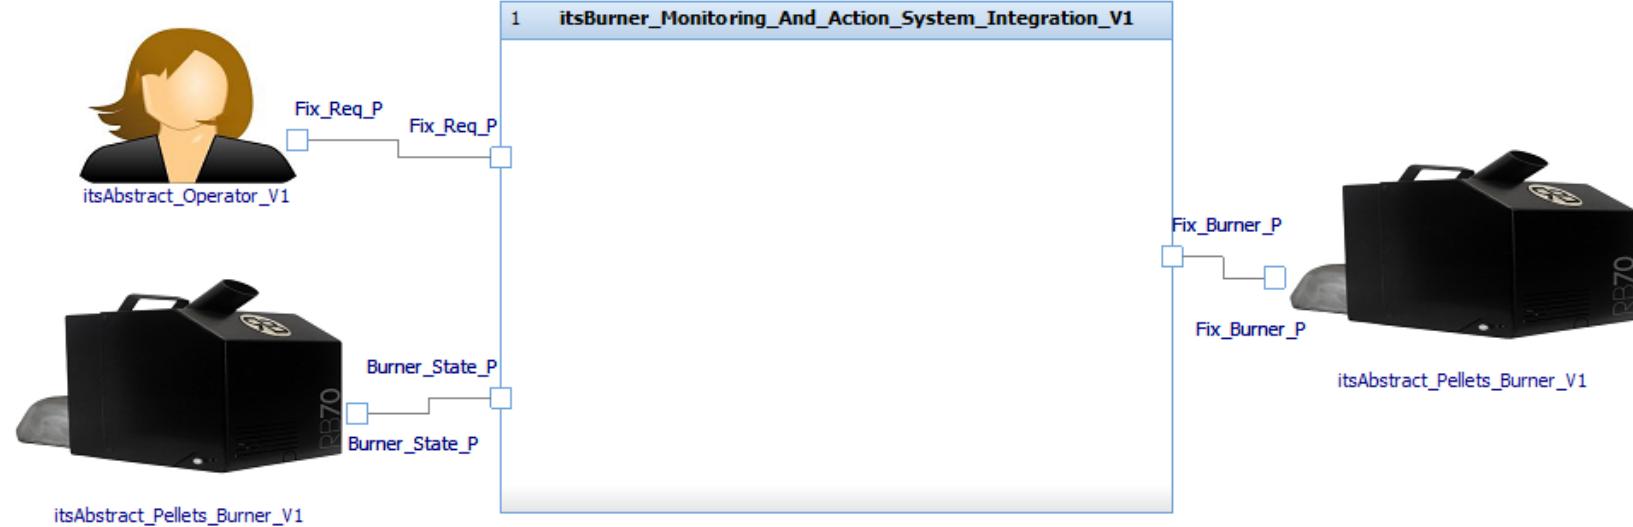

# To down select is to design

- P9 : To down select between valid design solutions is part of the design process
- P10 : To choose inputs and outputs equals a down select
- {P9, P10} => C4 : An inputs and outputs choice is part of the design

# To down select is to design

Assume:

- 4 different ways of communicating a fix request,
- 4 ways of getting to know the burner state and
- 4 ways of fixing the pellets burner;

=> 64 valid input/output sets

**We do not want to be forced to select a specific input/output set when writing top-level system requirements.**

# Requirements is not design-agnostic

- C2: A system requirements set, on all system levels, includes transformation of inputs into outputs
- C4 : An inputs and outputs choice is part of the design
- P8: Inputs and outputs from higher level systems must be conserved if the methodology *functional decomposition*

# Crash and burn – failure of P2

- P2 : *All requirements sets is design-agnostic*
- C5 : A requirements set is, in the general case, not design-agnostic when applying ***functional decomposition***.
- C5 => - P2
- *P2 can not be valid in a ***functional decomposition*** context.*

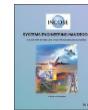

# Two premises that can't be true

- P1 : *All requirements sets is complete*

P1 can be true in theory, but not in practice

- P2 : *All requirements sets is design-agnostic*

P2 can not be true

# Be a good engineer and...

- Write a requirements set that is both complete and design-agnostic
- Is that possible?

# Part Two: Composition

- Where I argue that a system design approach based on functional ***composition*** can produce good requirements.
- Relax, this is the feel-good part.

# Change – Yes we can!

- P8: Inputs and outputs from higher level systems must be conserved if the methodology *functional decomposition* is used.
- It was the input and output conservation rule that got us into trouble.

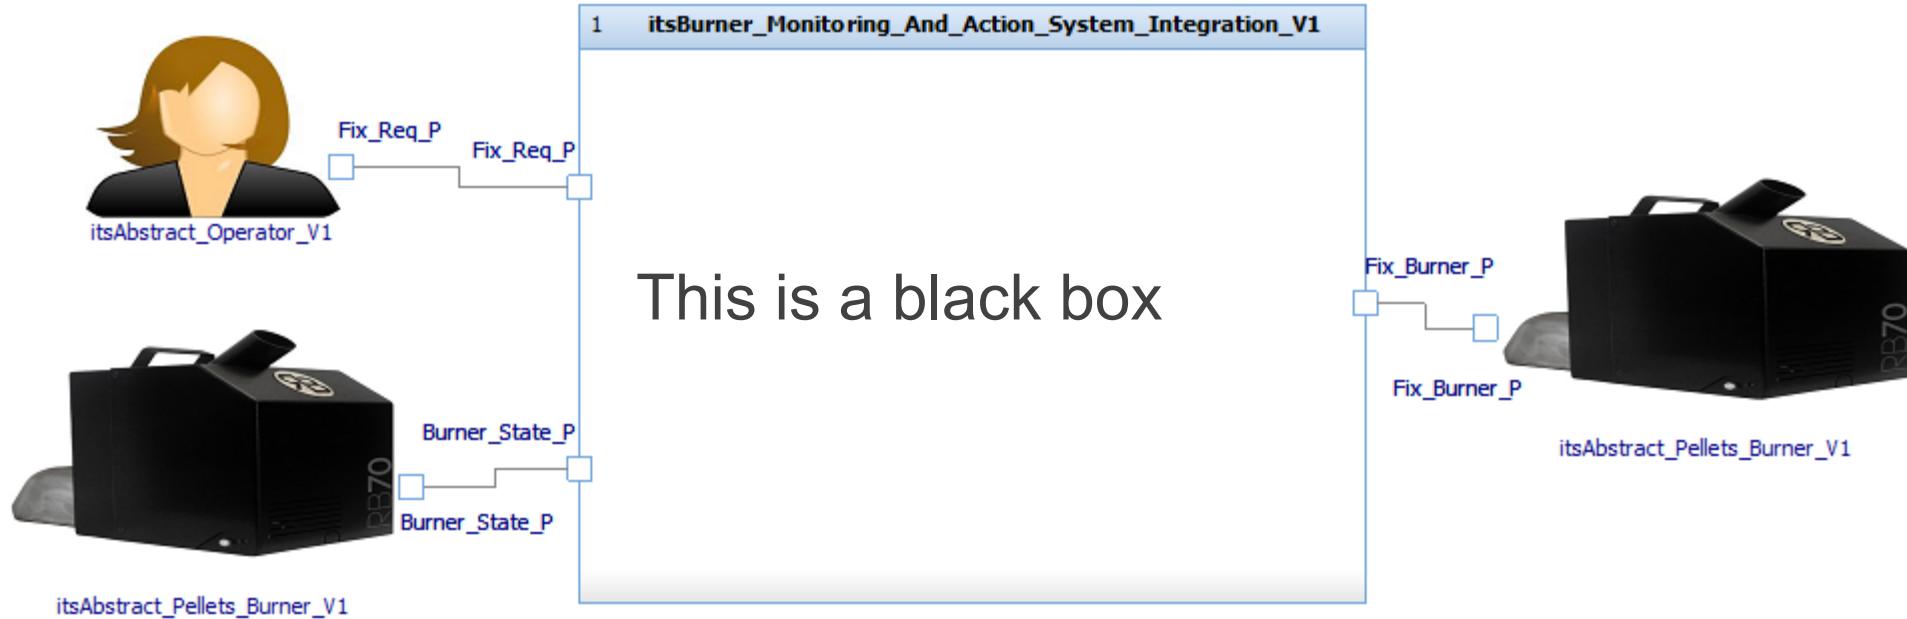

# Relaxations

- Relaxation: **Inputs and outputs from higher level system nodes do not need to be conserved.**
- Relaxation: **A black box description of a system and a white box description of the same system do not need to have identical inputs and outputs.**

# Top-level system black box

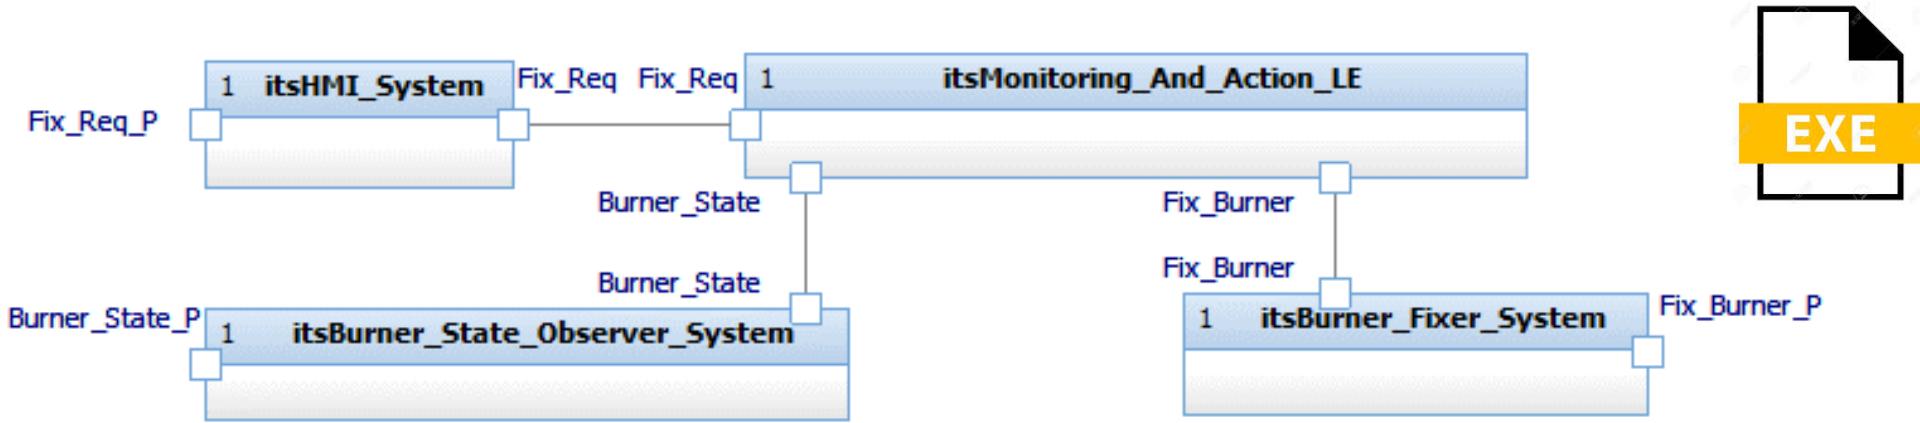

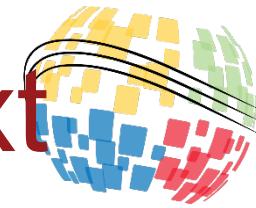

# Requirements example

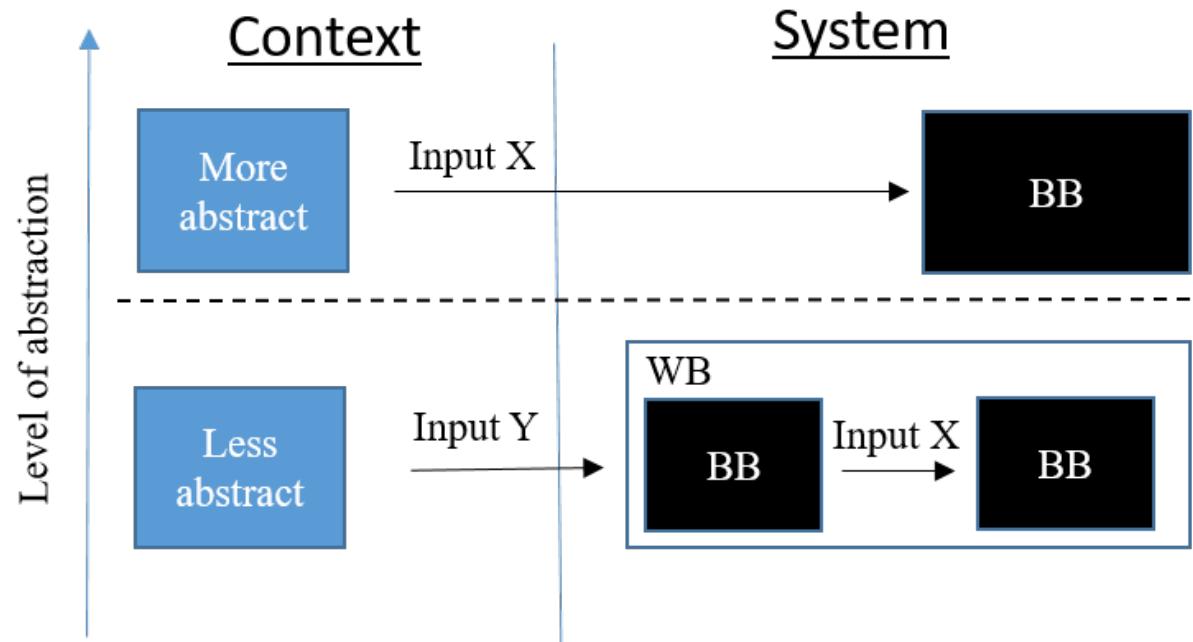

- **Pellets burner manual fix function**
  - R-001 If <fix pellets burner request> event shall a <pellets burner fix> action be performed
  - R-002 The <pellets burner manual fix function> shall be executed within a timeframe of 15 seconds

# Decomposition – no change in the context abstraction

An integrated system with three subsystems  
and a logical element leaf node

# Abstraction leap rule

As an example:  
Context entity = Pellets burner  
Input X = Burner state  
Input Y = Pellets consumption

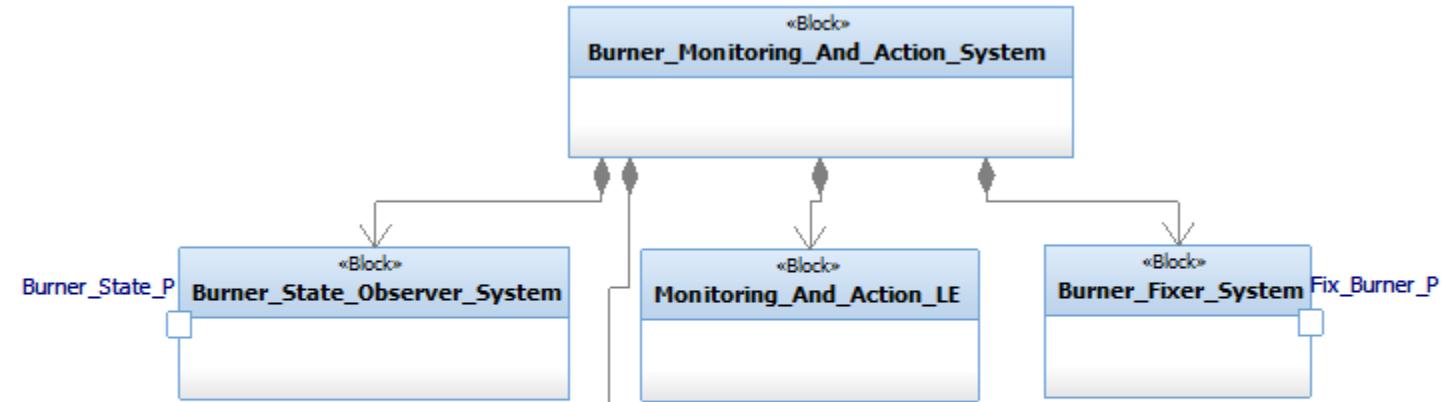

# Rules – from abstract to concrete

- If a set of inputs  $X$  on the black box description is exchanged for a set of inputs  $Y$  on the white box description there shall be a transformation of  $Y$  to  $X$  in the white box design so that  $X$  is used as an internal input.
- If a set of outputs  $X$  on the black box description is exchanged for a set of

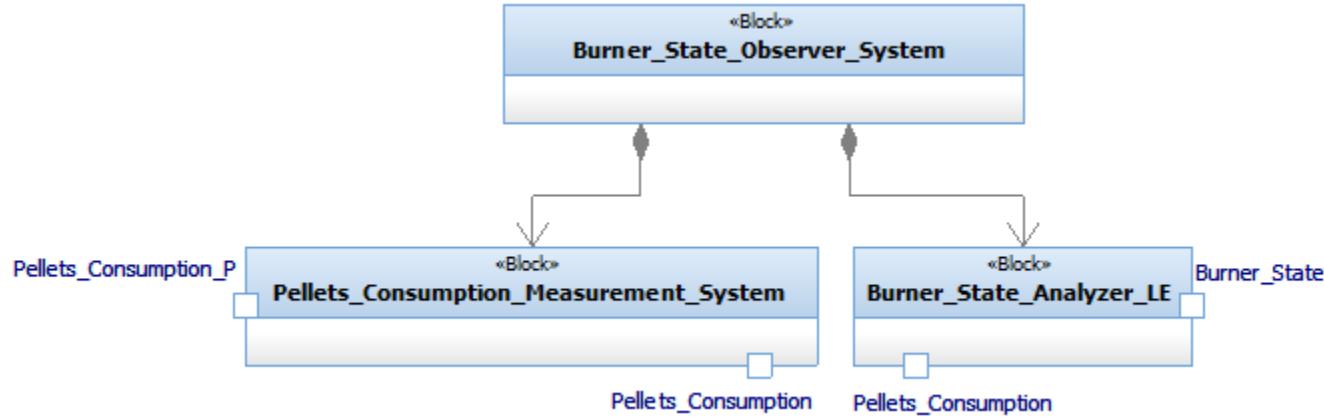

# Composition – a new level of abstraction

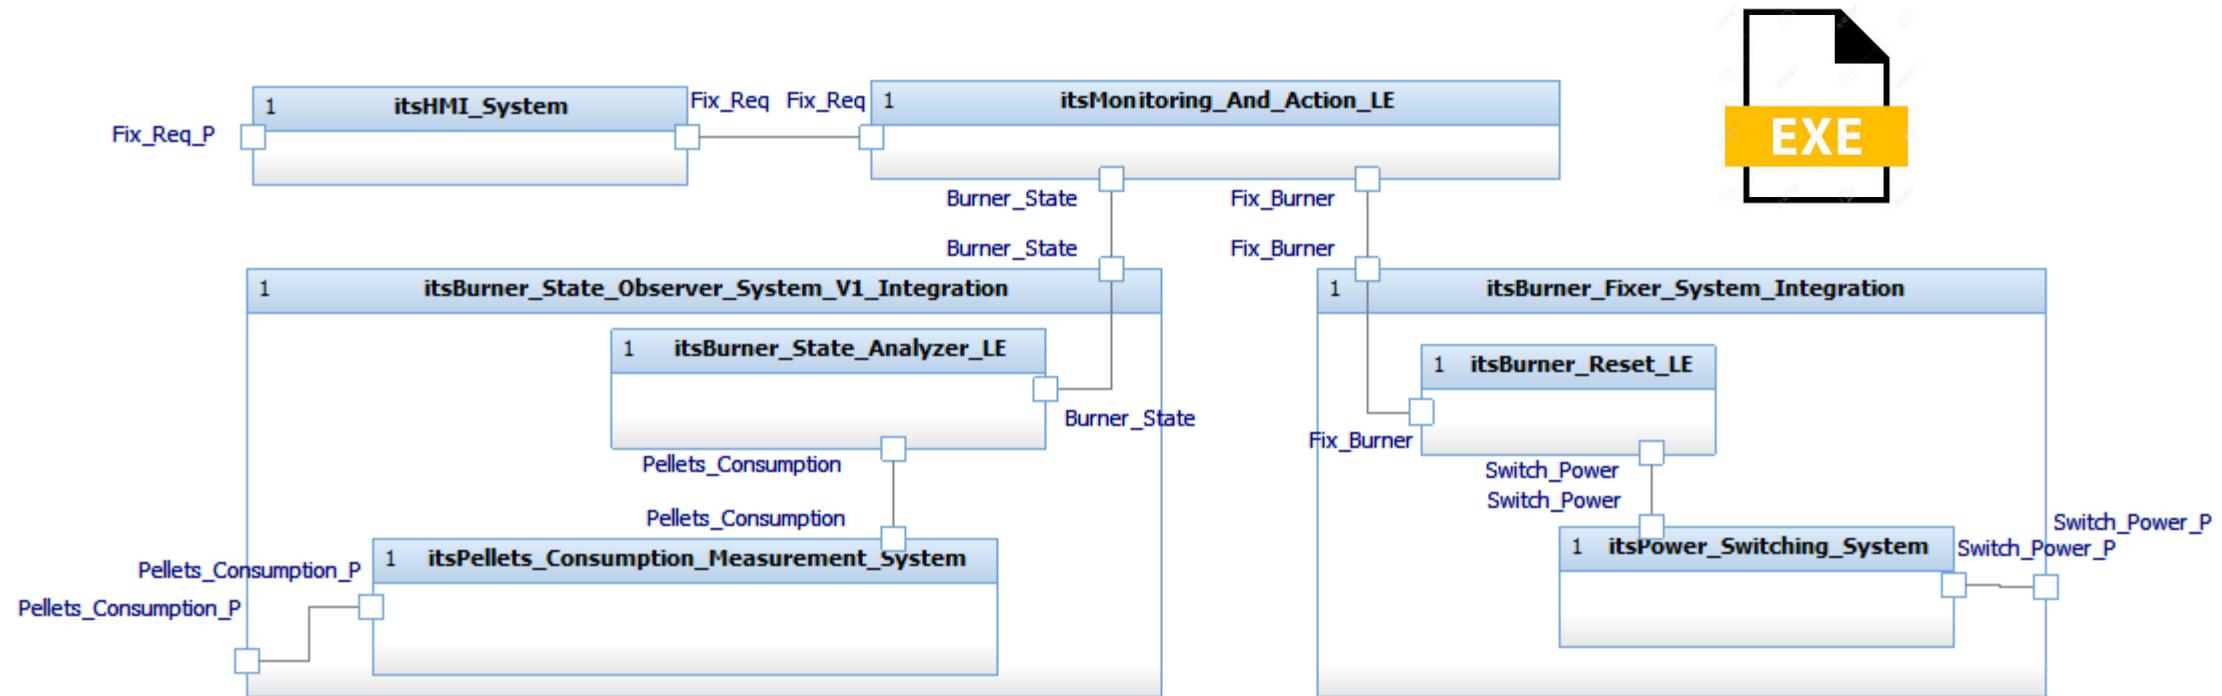

System design

Subsystem design

# Composition – a new level of abstraction

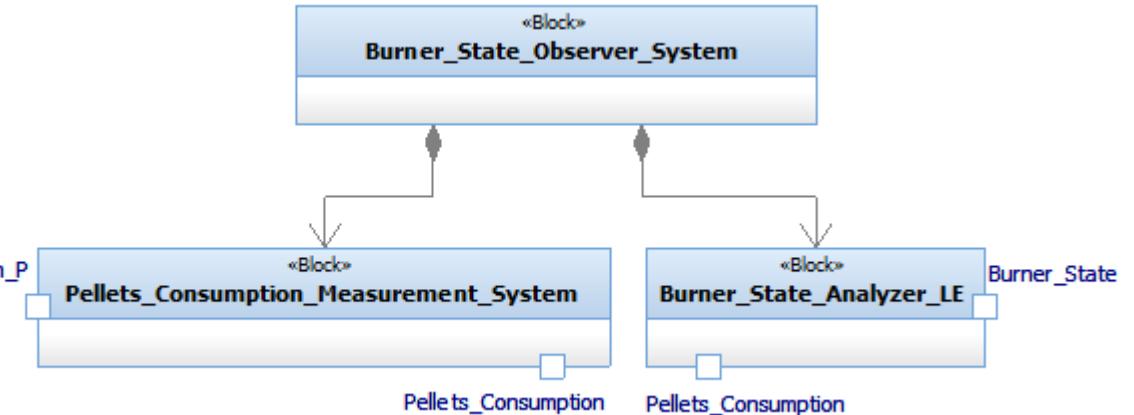

A new version of the integrated system

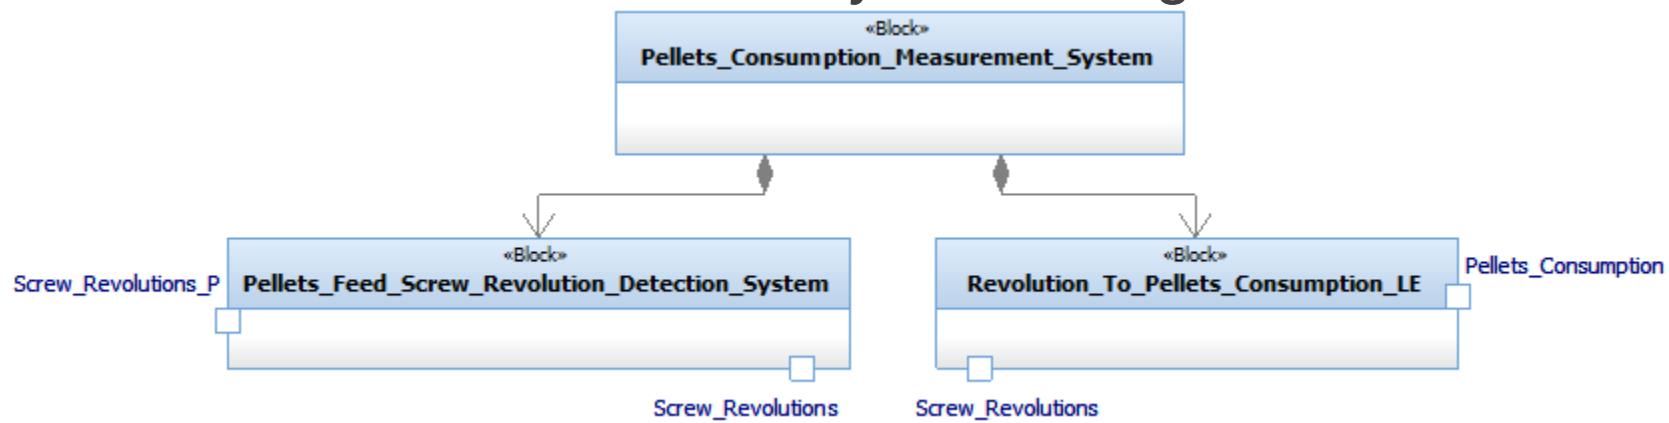

# Moving towards a realizable system

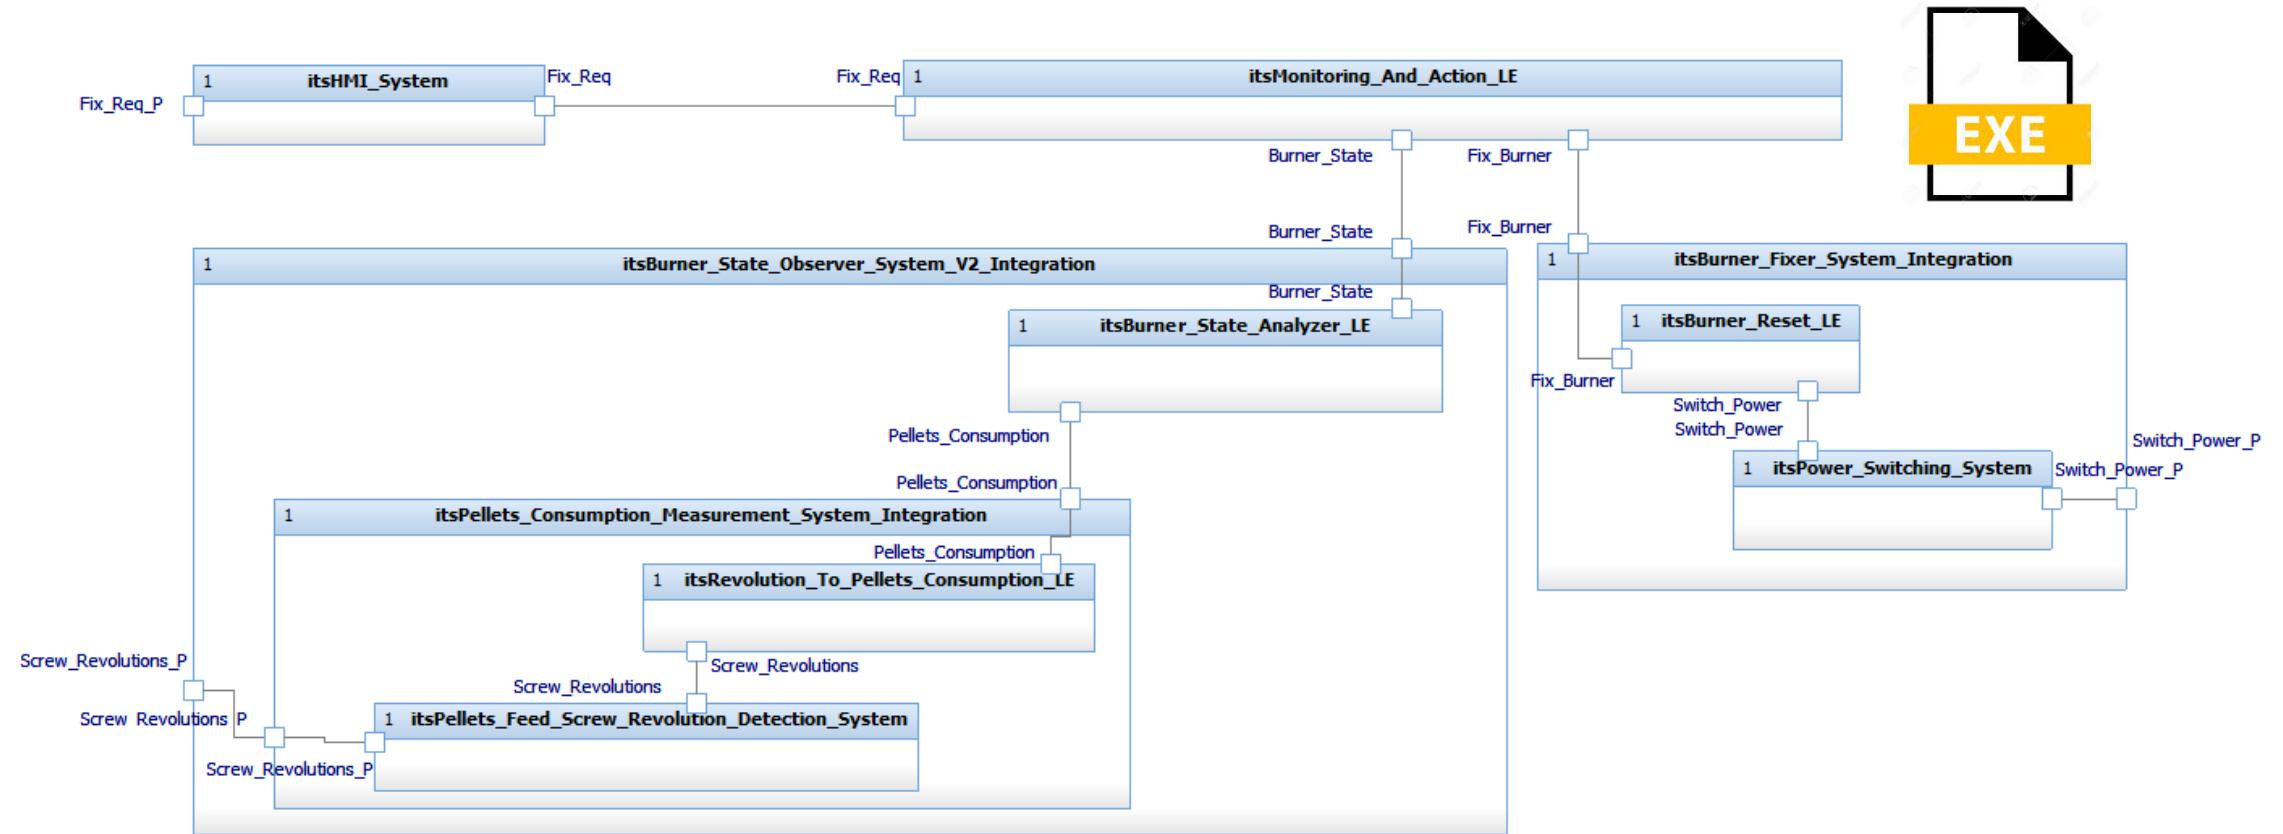

## System design

## Subsystem design

# Moving towards a realizable system

# Different versions of the integrated system

Burner state

Pellets consumption

Screw revolutions

**Continuous Design Integration**

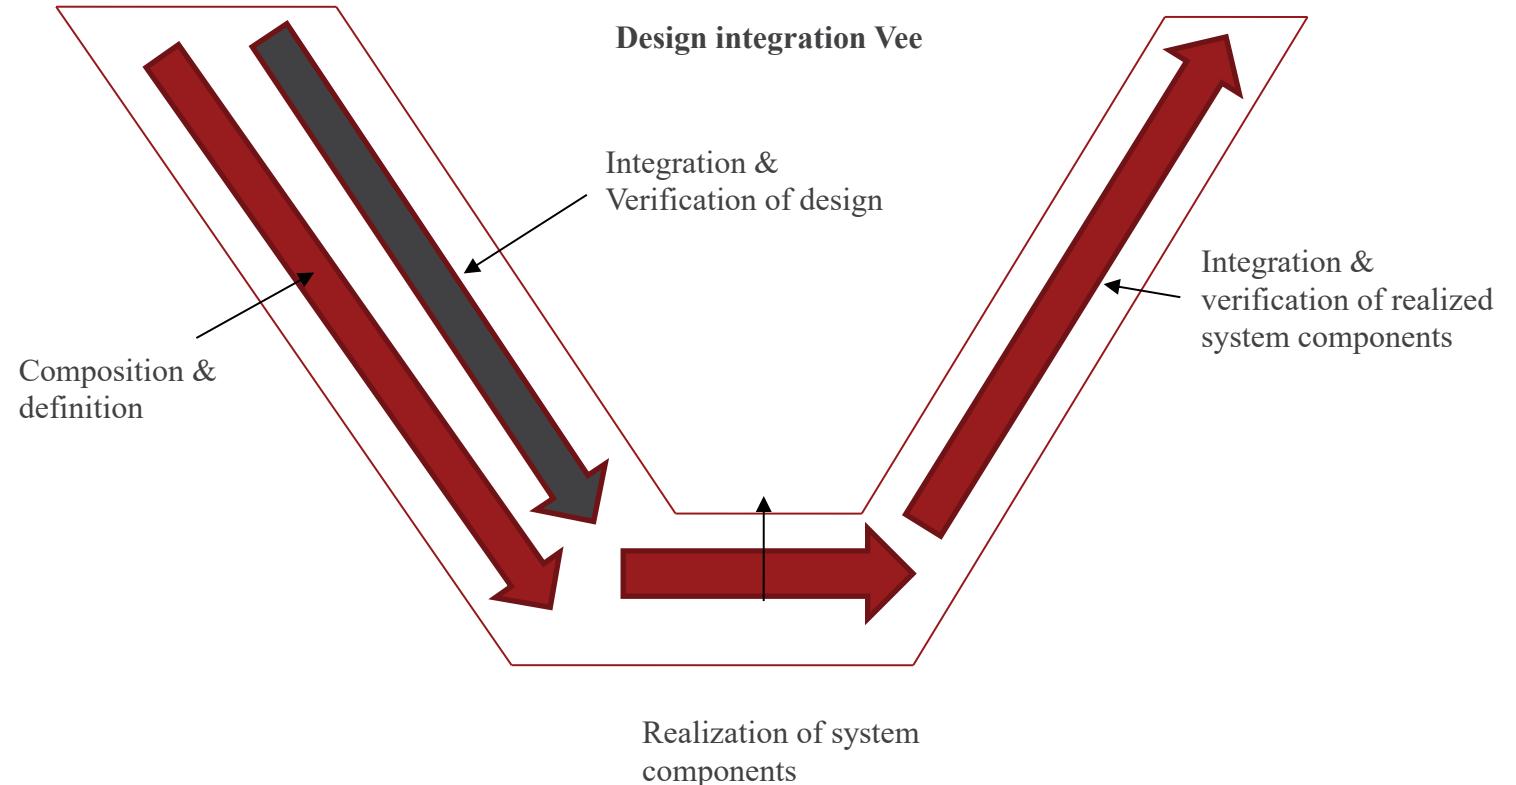

# Executable system models

- Functional composition makes it possible to fully specify the mapping of inputs to outputs on all system levels.
- The system design can be made executable (also in practice).
- An executable and composable design enables a **new development model**.

# Design integration Vee - model

# Key findings

- A top-down composition design methodology, including:
  - Executable design models and integration models
  - Very early and continuous design integration
  - Very early and continuous verification of design
  - Very early and continuous validation of

# The MBSE dream

28th Annual INCOSE international symposium  
Washington, DC, USA  
July 7 - 12, 2018

## Continuous Verification of MBSE

The diagram illustrates the 'Continuous Verification of MBSE' process. It starts with 'Stakeholder Requirement' at the top, which feeds into 'System Requirement' and 'System Architecture'. These requirements are then broken down into 'Sub-System A', 'Sub-System B', and 'Sub-System C'. Each sub-system undergoes 'Requirement' and 'Design' phases, which are mapped to 'MES' (Manufacturing Execution System) layers for 'Software', 'Electrical', and 'Mechanical' domains. The process then moves through 'Function verification', 'Function execution', 'Behavior execution', and 'Simulation & Verification' (highlighted with a red circle). These steps lead to 'System Validation' and finally 'System Integration & Verification'. A large arrow on the right indicates the 'Integration & Verification' process, which also feeds back into the 'Define & Decompose' phase of the next iteration. The diagram is set against a background of colored squares (blue, green, red) and includes a speaker's name, 'Zhang Xin Guo', and a title, 'Delivering Systems in the Age of Globalization'.

Washington, DC, USA

July 7 - 12, 2018

Paradigm shifting of Industry engineering 4.0

The diagram illustrates the paradigm shift from the Present to the Future in Industry engineering. In the Present, the process is 'Design-Built-Test', characterized by a V&V (Verification & Validation) loop and a 'Digital Geometry P/T' (Product Test) loop. In the Future, the process is 'Design-Virtual test-Built', characterized by a V&V loop and a 'Digital Geo/Fun/Per P/T' (Product Test) loop. The shift is marked by a large yellow arrow pointing from 'Present' to 'Future'. The time axis is indicated by a double-headed arrow labeled 'Time'.

# MBSE - a new hope

- **Functional composition and Design integration** can be a game changer for SE & MBSE

- MBSE is, in the context of top-down composition, not just a communication

# Questions?
